27195	7590	10/03/2006	EXAMINER HICKS, MICHAEL J	
AMIN. TUROCY & CALVIN, LLP 24TH FLOOR, NATIONAL CITY CENTER 1900 EAST NINTH STREET CLEVELAND, OH 44114			ART UNIT 2165	PAPER NUMBER

DATE MAILED: 10/03/2006

Please find below and/or attached an Office communication concerning this application or proceeding.

<b>Office Action Summary</b>	<b>Application No.</b> 10/600,797	<b>Applicant(s)</b> BRILL, ERIC D.	
	<b>Examiner</b> Michael J. Hicks	<b>Art Unit</b> 2165	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

#### Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

#### Status

- 1) ☒ Responsive to communication(s) filed on 14 August 2006.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

#### Disposition of Claims

- 4) ☒ Claim(s) 1-40, 42 and 43 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1-40, 42 and 43 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

#### Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☒ The drawing(s) filed on 20 June 2003 is/are: a) ☒ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

#### Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some \* c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
2. ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).
- \* See the attached detailed Office action for a list of the certified copies not received.

#### Attachment(s)

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☐ Information Disclosure Statement(s) (PTO/SB/08)  
Paper No(s)/Mail Date \_\_\_\_\_
- 4) ☐ Interview Summary (PTO-413)  
Paper No(s)/Mail Date. \_\_\_\_\_
- 5) ☐ Notice of Informal Patent Application
- 6) ☐ Other: \_\_\_\_\_

## DETAILED ACTION

1. Claims 1-40 and 42-43 Pending.

### *Response to Arguments*

2. Applicant's arguments, see response filed 8/14/2006, with respect to the rejection(s) of claim(s) 1-40 and 42-43 under USC 103(a) have been fully considered and are persuasive. Therefore, the rejection has been withdrawn. However, upon further consideration, a new ground(s) of rejection is made in view of Hansen in view of Chang et al.

Note that all of the deficiencies found in the combination of Hansen and Eitel will be addressed in combination of Hansen and Chang et al., below.

### *Claim Rejections - 35 USC § 103*

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

1. Claims 1-40 and 42-43 rejected under 35 U.S.C. 103(a) as being anticipated by Hansen et al. ("Using navigation data to improve IR functions in the context of Web search", Proceedings of the tenth international conference on Information and knowledge management; Atlanta,

Art Unit: 2165

Georgia, USA; Pages 135-142; ACM Press, 2001 and referred to hereinafter as Hansen) in view of Chang et al. ("A Multi-Engine Search Tool with Clustering", 6<sup>th</sup> International World Wide Web Conference, April 1997 and referred to hereinafter as Chang).

As per Claim 1, Hansen discloses a system that refines a general-purpose search engine, comprising (i.e. *"Traditional search engines like Lycos and Google now routinely return tens of thousands of resources per query...we propose narrowing search results by observing the browsing patterns of users during search tasks."* The preceding text excerpt clearly indicates a system that narrows the search results of/refines a traditional search engine/a general purpose search engine (e.g. Lycos, Google.) (Page 135, Column 1, Paragraph 2).

Hansen fails to disclose a component that identifies an entry point that includes a link utilized to access the general-purpose search engine and a tuning component that filters search query results of the general-purpose search engine based on criteria associated with the entry point.

Chang discloses a component that identifies an entry point that includes a link utilized to access the general-purpose search (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.)."* The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4) and a tuning component that filters search query results of the general-purpose search engine based on criteria associated with the entry point (i.e. *"The feedback of the selected topics also helps to customize the knowledge base, since there is a percentage of negligible words, like people names or mistyped words that are not common to other queries and are*

Art Unit: 2165

*weighed high in the weighting. But with user's feedback, we can identify what are the terms to be stressed and what are the ones that are irrelevant to the query...feedback of the same keywords can be repeated to strengthen their significance.*" The preceding text excerpt clearly indicates that the query results are filtered based on information from the knowledge base, which is associated with the entry point, and are used to further refine the knowledge base.) (Page 6, Paragraph 2).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include a component that identifies an entry point entry point that includes a link utilized to access the general-purpose search and a tuning component that filters search query results of the general-purpose search engine based on criteria associated with the entry point with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 2, Hansen discloses the criteria comprising one or more of a document property, a context parameter, and a configuration (i.e. "*...these schemes would involve the queries submitted by users together with the top L relevant pages returned by a given search engine.*" The preceding text excerpt clearly indicates that the criteria include queries submitted by users/keywords (e.g. a context parameter) and a URL (e.g. document property).) (Page 137, Column 1, Paragraph 4).

As per Claim 3, Hansen discloses the document property comprising one or more of a term that appears on a web page, a property of a Uniform Resource Locator (URL) identifying the web page, a property of a plurality of URLs that link to the web page, a property of a plurality of web pages that link to the web page, and a layout (i.e.

"...these schemes would involve the queries submitted by users together with the top  $L$  relevant pages returned by a given search engine." The preceding text excerpt clearly indicates that the document property includes queries submitted by users/a term that appears on a web page and the name/property of a URL.) (Page 137, Column 1, Paragraph 4).

As per Claim 4, Hansen discloses the context parameter comprising one of a word probability and a probability distribution (i.e. *"The group relation is captures by the triple  $(q_i, k, w_{ik})$ , where  $k$  denotes a group ID and  $w_{ik}$  is the probability that  $q_i$  belongs to group  $k$ . Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that a relevancy weight/probability distribution is used.) (Page 137, Column 2, Paragraph 4).

As per Claim 5, Hansen discloses the tuning component provided with training data to learn what properties of a document are indicative of the document being relevant to a user executing a search query from the entry point (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)."* The preceding text excerpt clearly indicates that training data is provided to help guide the cluster process (e.g. indicate what properties of a document are indicative of that document being relative to a user).) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).

As per Claim 6, Hansen discloses the tuning component configured to differentiate between a query result that is relevant to a search query context for a

Art Unit: 2165

group of users and a query result that is non-relevant to the search query context for the group of users (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that each URL/query result is given a relevance weight associated with the group used for the search. If the URL is relevant, it is assigned a high relevancy score, and if the URL is non-relevant, it is assigned a low relevancy score.) (Page 137, Column 2, Paragraph 4).

As per Claim 7, Hansen discloses the tuning component employs statistical analysis in connection with filtering the search query results (i.e. *"As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that statistical modeling/analysis is used in connection with page ranking/filtering of the search results.) (Page 138, Column 1, Paragraph 2).

As per Claim 8, Hansen discloses the tuning component generates one or more context parameters for a received query result (i.e. *"The group relation is captures by the triple  $(q_i, k, w_{ik})$ , where  $k$  denotes a group ID and  $w_{ik}$  is the probability that  $q_i$  belongs to group  $k$ . Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that a relevancy weight/context parameter is generated for a received query result.) (Page 137, Column 2, Paragraph 4), and then compare the generated context parameters with a relevant context parameter and a non-relevant context parameter to determine whether the query result is relevant (i.e. *"The group relation is*

*captures by the triple  $(q_i, k, w_{ik})$ , where  $k$  denotes a group ID and  $w_{ik}$  is the probability that  $q_i$  belongs to group  $k$ . Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ .*" The preceding text excerpt clearly indicates that in order to determine if the query result is associated with a group (e.g. group  $k$ ) the relevancy weight/context parameter is examined. Note that a high relevancy weight constitutes a relevant context parameter and a low relevancy weight constitutes a non-relevant context parameter. Further note that in order to determine if the query result is related to the group, the relevancy weight/context parameter for the query result must be compared to low and high relevancy weights.) (Page 137, Column 2, Paragraph 4).

As per Claim 9, Hansen discloses the tuning component further ranks the query results (i.e. *"Our clustering can also be used to modify the rankings of results from a traditional search engine."* The preceding text excerpt clearly indicates that the clustering/filtering is used to improve ranking/rank query results.) (Page 138, Column 1, Paragraph 3).

As per Claim 10, Hansen discloses the ranking determined by the degree of relevance of the query result to a relevant data set and a non-relevant data set, the relevance is determined via one of a similarity measure and a confidence interval (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ...As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that that ranking is determined by a relevancy score/similarity measure assigned to the URL by comparing it to a group of queries (e.g. group  $k$ ). Note that not all of the pages in the group that the URL is being compared to are relevant as some may have a low relevancy

Art Unit: 2165

score in the set, therefore the group (e.g. group k) constitutes both a set of relevant data, and a set of non-relevant data.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 2).

As per Claims 11 and 20, Hansen discloses the ranking order comprising one of ascending and descending, from the most relevant result to the least relevant result (i.e. *"Here, we arrange the query groups and the URLs by weight, with the most relevant appearing at the top."* The preceding text excerpt clearly indicates that the results are sorted in descending order, with the most relevant results at the top.) (Page 138, Column 1, Paragraph 2).

As per Claim 12, Hansen discloses the tuning component configured for a plurality of entry points associated with one or more groups of users (i.e. *"...we present three search sessions (each initiated by a different user)..."* The preceding text excerpt clearly indicates that entry points for multiple groups of users may be defined.) (Page 137, Column 1, paragraph 3).

As per Claim 13, Hansen discloses a system that tunes a general-purpose search engine, comprising (i.e. *"Traditional search engines like Lycos and Google now routinely return tens of thousands of resources per query...we propose narrowing search results by observing the browsing patterns of users during search tasks."* The preceding text excerpt clearly indicates a system that narrows the search results of/tunes a traditional search engines/a general purpose search engine (e.g. Lycos, Google).) (Page 135, Column 1, Paragraph 2): a filter component that parses relevant and non-relevant general-purpose search engine content results based on training data (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index j range from 1 to the number of URLs seen in the training data, J (which might include URLs from a content hierarchy)...When a new user*

Art Unit: 2165

*initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs arranged in a display like that in Figure 4."* The preceding text excerpt clearly indicates training data is used to parse general search engine results for related query groups/an entry point.) (Figure 4; Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2); and a ranking component that sorts the filtered results in accordance with the training data for presentation to a user (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index j range from 1 to the number of URLs seen in the training data, J (which might include URLs from a content hierarchy)...These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that a ranking component is present which ranks data based on/in accordance with the content hierarchy/training data. Note that Figure 4 illustrated the results being displayed to a user.) (Figure 4; Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2).

Hansen fails to disclose that the content results are for an entry point that provides a link employed to traverse the general purpose search engine.

Chang discloses that the content results are for an entry point that provides a link employed to traverse the general purpose search engine (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.)."* The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include that the content results are for an entry point that provides a link employed to traverse the

general purpose search engine with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 14, Hansen discloses the filter component parsing the results as a function of one or more of a document property, a context parameter, and a configuration associated with the entry point (i.e. *"...we consider improving search results by first forming groups of queries based on the similarity of their associated search sessions...This has the effect of reducing spurious associations between queries...these schemes would involve the queries submitted by users together with the top L relevant pages returned by a given search engine."* The preceding text excerpt clearly indicates that a filter component exists which parses the results using queries submitted by users/keywords (e.g. a context parameter) and a URL (e.g. document property).) (Page 137, Column 1, Paragraphs 3-4)

As per Claim 15, Hansen discloses the filter component trained to differentiate between a relevant and a non-relevant result via the training data (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)...Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that, using training data, each URL/query result is given a relevance weight associated with the group used for the search. If the URL is relevant, it is assigned a high relevancy score, and if the URL is non-relevant, it is assigned a low relevancy score.) (Page 137, Column 2, Paragraph 4).

As per Claim 16, Hansen discloses the training data comprising a set of relevant data associated with a search context of a user for the entry point and a set of non-relevant data comprising random data unrelated to the search context of the user for the entry point (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)."* The preceding text excerpt clearly indicates that a set of training data, the portion of which that is associated with the search context of the user for the entry point constituting the set of relevant data, and the portion of which that is irrelevant to the search context of the user for the entry point constituting the set of non-relevant data, exists and are used to help determine the relevancy of a search result. Note that the set of unrelated data comes from an existing data hierarchy, and can therefor be considered random.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).

As per Claim 17, Hansen discloses the filter component employs statistical analysis to determine whether a result is relevant or non-relevant to the entry point (i.e. *"As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that statistical modeling/analysis is used in connection with page ranking/filtering of the search results which determine relevancy. Note from above that the triple referred to contain a relevancy score.) (Page 138, Column 1, Paragraph 2).

As per Claim 18, Hansen discloses the ranking component employs a technique to determine the degree of relevance of the query results with respect to a relevant data

Art Unit: 2165

set and a non-relevant data set (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates that a set of, the portion of which that is associated with the search context of the user for the entry point constituting the set of relevant data, and the portion of which that is irrelevant to the search context of the user for the entry point constituting the set of non-relevant data, exists and are used to help determine the relevancy of a query result.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).*

As per Claim 19, Hansen discloses the technique comprising one of a similarity measure and a confidence interval (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ...As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that that ranking/relevancy is determined by a relevancy score/similarity measure assigned to the URL by comparing it to a group of queries (e.g. group  $k$ ).)(Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 2).

As per Claim 21, Hansen discloses the ranking performed on the relevant query results, wherein the non-relevant results are discarded (i.e. *"For each group, we select the most relevant URLs arranged in a display like that in Figure 4. Here, we arrange the query groups and the URLs by weight, with the most relevant appearing at the top."* The preceding text excerpt clearly indicates that only the most relevant URLs/results are displayed, while the less or non-relevant results are discarded.) (Page 138, Column 1, Paragraph 2).

As per Claim 22, Hansen discloses a method to filter and rank general-purpose search engine results associated with an entry point, comprising (i.e. *"These triples can be used by a search engine to improve page rankings. When a new user initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs arranged in a display like that in Figure 4."* The preceding text excerpt clearly indicates a method for filtering and ranking of general-purpose search engine results associated with an entry point. Note that the entry point is associated with the groups mentioned in the quotation and as referenced above.) (Page 138, Column 1, Paragraph 2); and ranking the general-purpose search engine results (i.e. *"These triples can be used by a search engine to improve page rankings. When a new user initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs arranged in a display like that in Figure 4."* The preceding text excerpt clearly indicates that the general-purpose search engine results are ranked.) (Page 138, Column 1, Paragraph 2).

Hansen fails to disclose executing a query search with the general purpose search engine accessed through a link associated with the entry point and filtering the general-purpose search engine results by tuning the general purpose search engine based on the entry point.

Chang discloses executing a query search with the general purpose search engine accessed through a link associated with the entry point (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.)."* The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a

Art Unit: 2165

search engine) exists.) (Page 2, Paragraph 4) and filtering the general-purpose search engine results by tuning the general purpose search engine based on the entry point (i.e. *"The feedback of the selected topics also helps to customize the knowledge base, since there is a percentage of negligible words, like people names or mistyped words that are not common to other queries and are weighed high in the weighting. But with user's feedback, we can identify what are the terms to be stressed and what are the ones that are irrelevant to the query...feedback of the same keywords can be repeated to strengthen their significance."* The preceding text excerpt clearly indicates that the query results are filtered based on information from the knowledge base, which is associated with the entry point, and are used to further refine the knowledge base.) (Page 6, Paragraph 2).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include executing a query search with the general purpose search engine through the entry point and filtering the general-purpose search engine results by tuning the general purpose search engine based on the entry point with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 23, Hansen discloses employing a statistical hypothesis to determine whether a result is relevant or non-relevant to a search context of the entry point (i.e. *"As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that statistical modeling/a statistical hypothesis is used in connection with page ranking of the search results, which determines relevancy. Note from above that the triple referred to contain a relevancy score.) (Page 138, Column 1, Paragraph 2).

As per Claim 24, Hansen discloses the statistical hypothesis employing a threshold in connection with a probability distribution for relevant data and a probability distribution for non-relevant data (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ...*As mentioned above, sets of such triples constitute the parameters in a statistical model for the search session...For each such group, we select the most relevant URLs..." The preceding text excerpt clearly indicates that a threshold to determine which are the most relevant URLs exists and that a relevancy weight/probability distribution of a document is calculated for each group, some of which are relevant to the search, and some of which are not.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2), wherein respective word probabilities are generated for the search query results and compared to the threshold (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ...*For each such group, we select the most relevant URLs..." The preceding text excerpt clearly indicates that in order for a URL/result to be considered most relevant it's relevancy weight/probability distribution must be first calculated, then compared to the threshold.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2), the probability distribution for relevant data and the probability distribution for non-relevant data to determine whether the results are relevant or non-relevant (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that the relevancy score/probability distribution is used to determine which results are relevant and which results are non-relevant.) (Page 137, Column 2, Paragraph 4).

As per Claim 25, Hansen discloses the threshold employed to bias the decision to mitigate one of a result being deemed non-relevant when the result is relevant and a result being deemed relevant when the result is non-relevant (i.e. *"We capture the interesting part of the search path in a search session, which is the user's query together with the URLs of the Web sites they visit in response to their query... Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ... As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions."* The preceding text excerpt clearly indicates that because the results are collected over many search sessions, and are collected from which URLs users visit, if one users visits a non-relevant URL in response to a search, this URL will only be determined as relevant in response to one search session. Unless the data from the collected search sessions also indicate the non-relevant URL, its relevancy weight will not be greatly affected, therefore mitigating/lessening the impact. Also not that, in much the same way, relevant URLs relevancy weights will not be greatly affected as a result of being deemed non-relevant in one particular search session. The data from many collected search sessions is needed to markedly influence a relevancy weight.) (Page 135, Column 2, Paragraph 2; Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 2).

As per Claim 26, Hansen discloses employing a probability distribution analysis or machine learning in connection with the filtering and ranking, wherein suitable probability distributions include a Bernoulli, a binomial, a Pascal, a Poisson, an arcsine, a beta, a Cauchy, a chi-square with N degrees of freedom, an Erlang, a uniform, an exponential, a gamma, a Gaussian-univariate, a Gaussian-bivariate, a Laplace, a log-

Art Unit: 2165

normal, a rice, a Weibull and a Rayleigh distribution (i.e. *"The same kind of Poisson structure used for the collection of URLs in a search session is applied to the query terms."* The preceding text excerpt clearly indicates that a poisson distribution is used.) (Page 11, Column 1, Paragraph 6), and the machine learning can classify based on one or more of a word occurrence, a distribution, a page layout, an inlink, and an outlink (i.e. *"A natural prior for our coefficients  $\lambda_{ij}$  (the relevance weights) is a Gamma distribution."* The preceding text excerpt clearly indicates a distribution is used to classify the relevancies.) (Page 141, Column 1, Paragraph 5).

As per Claim 27, Hansen discloses employing a statistical analysis to rank search query results (i.e. *"As mentioned above, sets of such triples constitute the parameters in a statistical model for the search sessions. These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that statistical modeling/analysis is used in connection with page ranking of the search results.) (Page 138, Column 1, Paragraph 2).

As per Claim 28, Hansen discloses the ranking comprising one of generating word probabilities and employing a confidence interval to determine relevance, and generating a similarity measure comprising one of a cosine distance, the Jaccard coefficient, an entropy-based measure, a divergence measure and/or a relative separation measure to determine similarity (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that a weight is given to each site to identify how closely it is related to a group  $k$ , and which is used in ranking. Note that the weights are based on the search terms, as in Figures 3 and

Art Unit: 2165

4, which therefore indicates that word probabilities are used to assign the weights and ranks.) (Figures 3, 4; Page 137, Column 2, Paragraph 4).

As per Claim 29, Hansen discloses a method to manually customize a general-purpose search engine for an entry point, comprising (i.e. *"Traditional search engine...now routinely return tens of thousands of resources per query...it has typically required the user to report details of their search and manually tag pages according to their relevance..."* The preceding text excerpt clearly indicates that a general purpose search engine is manually customized to create an entry point (e.g. basis to narrow search results, and return more accurate results) by having users tag results for relevance.) (Page 135, Column 1, Paragraph 2; Page 137, Column 2, Paragraph 1): providing a set of relevant data to train a component to discern query results relevant to a search context of a user employing the entry point (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates a set of data, the portion of which is related to the query constituting the set of relevant data, which guides the cluster process/is used to discern query results relevant to a search context of a user employing the entry point. Note that URLs relevance will be measured by a relevancy score which pertains to how relevant the data is to the groups in the training set. A high relevancy score indicates a relevant URL.) (Page 137, Column 2, Paragraph 3); providing a set of non-relevant data to train the component to discern query results unrelated to the search context (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates a set of data, the portion of which is unrelated to the query constituting the set of non-relevant data, which guides the cluster process/is used to discern**

Art Unit: 2165

query results non-relevant to a search context of a user employing the entry point. Note that URLs relevance will be measured by a relevancy score which pertains to how relevant the data is to the groups in the training set. A low relevancy score indicates an unrelated URL.) (Page 137, Column 2, Paragraph 3), the set of relevant data and the set of non-relevant data are manually provided; and determining whether a query result is relevant to the search context based on the set of non-relevant data (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates that the set of relevant data and the set of non-relevant data are manually provided and employed to guide the clustering process/determine whether a query result is relevant to a search context.) (Page 137, Column 2, Paragraph 3).*

Hansen fails to disclose the entry point provides a link employed to access the general purpose search engine.

Chang discloses the entry point provides a link employed to access the general purpose search engine (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.)."* The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include the entry point provides a link employed to access the general purpose search engine with

Art Unit: 2165

the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 30 and 35, Hansen discloses the set of relevant data comprising data associated with the search context of the user for the entry point (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates that a set of data, the portion of which that is associated with the search context of the user for the entry point constituting the set of relevant data, exists.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).*

As per Claim 31 and 36, Hansen discloses the set of non-relevant data comprising random data unrelated to the search context of the user for the entry point (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates that a set of data, the portion of which that is unrelated with the search context of the user for the entry point constituting the set of non-relevant data, exists.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).*

As per Claim 32 and 37, Hansen discloses providing information to associate respective query results with the entry point (i.e. *"Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that*

Art Unit: 2165

*determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ...For each such group, we select the most relevant URLs...*" The preceding text excerpt clearly indicates that the relevancy weight is used to associate query results with the relevant group/the entry point) (Page 138, Column 1, Paragraph 2).

As per Claim 33 and 38, Hansen discloses the set of relevant data and the set of non-relevant data employed to train the component to learn the features that differentiate relevant data from non-relevant data (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)." The preceding text excerpt clearly indicates that the set of relevant data and the set of non-relevant data are used as a set of training data to identify relevant data.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraph 1).*

As per Claim 34, Hansen discloses a method to automatically customize a general-purpose search engine for an entry point, comprising (i.e. *"Traditional search engine...now routinely return tens of thousands of resources per query...we propose narrowing search results by observing browsing patterns of users during search tasks."* The preceding text excerpt clearly indicates that a general purpose search engine is automatically customized to create an entry point (e.g. basis to narrow search results, and return more accurate results) by observing users during search tasks.) (Page 135, Column 1, Paragraph 2): recording a query result selected by a user as relevant (i.e. *"We capture the interesting part of the search path in a search session, which is a user's query together with the URLs of the Web pages they visit in response to their query...by combining search sessions with queries in a given group, we can better identify relevant URLs."* The preceding text excerpt clearly indicates that URLs/query results selected by a user are used as data to identify relevant

Art Unit: 2165

URLs, therefore some of them will be marked as relevant.) (Page 135, Column 2, Paragraph 2; Page 137, Column 1, Paragraph 3); recording a higher ranked query results, wherein a lower ranked result is selected by the user, as non-relevant (i.e. "...PageRank is based on the amount of time a "random surfer" would spend on each page." The preceding text excerpt clearly indicates that if the browser spends time on a given web page, it increases the relevancy of that web page (e.g. marks it as relevant) and decreases the relevancy of other pages, which may be considered more relevant (e.g. marks a relevant page as non-relevant).) (Page 137, Column 2, Paragraph 2); and providing the recorded results to automatically train the filter to discriminate between results relevant to a search context of the user for the entry point and results non-relevant to the search context (i.e. "We capture the interesting part of the search path in a search session, which is a user's query together with the URLs of the Web pages they visit in response to their query...Implicit in our approach is a form of query clustering that combines similar search terms on the basis of Web pages visited during a search session. These clusters are then used to improve the display of search engine results." The preceding text excerpt clearly indicates that previous query results and selections are recorded and added to the set of data used to discriminate between relevant results and non-relevant results.) (Page 135, Column 2, Paragraph 2).

Hansen fails to disclose executing a query search via the entry point that includes a link employed to route to the general purpose search engine.

Chang discloses executing a query search via the entry point that includes a link employed to route to the general purpose search engine (i.e. "The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.). " The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include executing a query search via the entry point that includes a link employed to route to the general purpose search engine with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 39, Hansen discloses the query results selected via a click thru technique employing a mouse to select a link associated with the query result by clicking on the link (i.e. "...users click through data to discover disjoint sets of similar URLs" The preceding text excerpt clearly indicates results and URLs are viewed using a click-through technique incorporating a mouse.) (Page 141, Column 1, Paragraph 2).

As per Claim 40, Hansen discloses generating a word probability distribution for the relevant recorded results and a word probability distribution for the non-relevant recorded results (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)...Then, for each group, we identify a number of relevant URLs. This is described by the triple  $(k, u_j, \lambda_{kj})$  where  $u_j$  is a URL and  $\lambda_{kj}$  is a weight that determines how likely it is that  $u_j$  is associated with the queries belonging to group  $k$ ."* The preceding text excerpt clearly indicates that a weight is given to each site to identify how closely it is related to a group  $k$ , and which is used in ranking. Note that the weights are based on the search terms, as in Figures 3 and 4, which therefore indicates that word probabilities are used to assign the weights and ranks. Note that the weights are generated for each group and that the data set is

Art Unit: 2165

comprised of a portion that is associated with the search context of the user for the entry point and constitutes the set of relevant data, and a portion that is irrelevant to the search context of the user for the entry point and constitutes the set of non-relevant data.) (Figures 3, 4; Page 137, Column 2, Paragraph 4).

As per Claim 42, Hansen discloses a computer readable medium storing computer executable components that tunes a general-purpose search engine to improve context search query results, comprising (i.e. *"Traditional search engines like Lycos and Google now routinely return tens of thousands of resources per query...we propose narrowing search results by observing the browsing patterns of users during search tasks."* The preceding text excerpt clearly indicates a system that narrows the search results of/tunes a traditional search engines/a general purpose search engine (e.g. Lycos, Google).) (Page 135, Column 1, Paragraph 2): a component that filters the general-purpose search engine results based on training data sets associated with the search context of a user (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which might include URLs from a content hierarchy)...When a new user initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs arranged in a display like that in Figure 4."* The preceding text excerpt clearly indicates training data associated with the search context of a user is used to filter general purpose search engine results.) (Figure 4; Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2); and a component that ranks the general-purpose search engine results according to the similarity of the search engine results to the training data sets (i.e. *"To help guide the cluster process, we also introduce labeled data from an existing topic hierarchy that contains over 1.2 million Web sites...We let the index  $j$  range from 1 to the number of URLs seen in the training data,  $J$  (which*

Art Unit: 2165

*might include URLs from a content hierarchy)...These triples can be used by a search engine to improve page rankings."* The preceding text excerpt clearly indicates that a ranking component is present which ranks data based on/in accordance with similarity to the content hierarchy/training data.) (Page 137, Column 2, Paragraph 4; Page 138, Column 1, Paragraphs 1-2).

Hansen fails to disclose an entry point that provides a link utilized to arrive at the general-purpose search engine.

Chang discloses an entry point that provides a link utilized to arrive at the general-purpose search engine (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos, WebCrawler, Magellan, etc.)."* The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4).

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include an entry point that provides a link utilized to arrive at the general-purpose search engine with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

As per Claim 43, Hansen discloses a system that filters and ranks general-purpose search engine results, comprising (i.e. *"These triples can be used by a search engine to improve page rankings. When a new user initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs*

Art Unit: 2165

*arranged in a display like that in Figure 4.*" The preceding text excerpt clearly indicates a method for filtering and ranking of general-purpose search engine results associated with an entry point. Note that the entry point is associated with the groups mentioned in the quotation and as referenced above.) (Page 138, Column 1, Paragraph 2): means for filtering general-purpose search engine results to determine whether a query result is relevant to a search context of a group of users (i.e. *"...we consider improving search results by first forming groups of queries based on the similarity of their associated search sessions...This has the effect of reducing spurious associations between queries."* The preceding text excerpt clearly indicates that search results from a search engine are improved/filtered based on search context associated with a group of users.) (Page 137, Column 1, Paragraphs 3-4), and means for ranking the general-purpose search engine results based on a relevance of the general-purpose search engine results to the search context of the group of users (i.e. *"These triples can be used by a search engine to improve page rankings. When a new user initiates a search, we present them with a display of query groups most related to their search terms. For each such group, we select the most relevant URLs arranged in a display like that in Figure 4."* The preceding text excerpt clearly indicates that the general-purpose search engine results are ranked based on relevance to the search terms/context of the users.) (Page 138, Column 1, Paragraph 2).

Hansen fails to disclose an entry point that includes a link employed to navigate to the general purpose search engine and means for ranking the general-purpose search engine results based on a relevance of the general-purpose search engine results to the search context of the entry point.

Chang discloses an entry point that includes a link employed to navigate to the general purpose search engine (i.e. *"The implementation of the system is based on the multi-engine search architecture. Under this architecture, the system receives a user's query as a list of keywords and redirects the query to other search engines (which include Altavista, Infoseek, Lycos,*

Art Unit: 2165

*WebCrawler, Magellan, etc.). " The preceding text excerpt clearly indicates that a link used to forward users queries to a remote commercial search engine (e.g. an entry point to a search engine) exists.) (Page 2, Paragraph 4) and means for ranking the general-purpose search engine results based on a relevance of the general-purpose search engine results to the search context of the entry point (i.e. "The feedback of the selected topics also helps to customize the knowledge base, since there is a percentage of negligible words, like people names or mistyped words that are not common to other queries and are weighed high in the weighting. But with user's feedback, we can identify what are the terms to be stressed and what are the ones that are irrelevant to the query...feedback of the same keywords can be repeated to strengthen their significance." The preceding text excerpt clearly indicates that the query results are filtered based on information from the knowledge base, which is associated with the entry point, and are used to further refine the knowledge base.) (Page 6, Paragraph 2).*

It would have been obvious to one skilled in the art at the time of Applicants invention to modify the teachings of Hansen with the teachings of Chang to include an entry point that includes a link employed to navigate to the general purpose search engine and means for ranking the general-purpose search engine results based on a relevance of the general-purpose search engine results to the search context of the entry point with the motivation of forwarding search queries to search engines and refining the query results to direct the searching towards the intended purpose (Page 2, Paragraphs 4-5).

2. Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP

Art Unit: 2165

§ 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the date of this final action.
